Computing the light character

The function `beam_interval` divides the rotation period by the number of flashes:

```
def beam_interval(rotation_seconds, flashes):
    """Seconds between flashes as seen from the sea."""
    if flashes <= 0:
        raise ValueError("a light needs at least one flash")
    return rotation_seconds / flashes

for name, (period, n) in LIGHTS.items():
    print(f"{name:<12} {beam_interval(period, n):5.1f} s")
```

Each station is described by a small JSON record:

```
{
  "station": "Skarvik",
  "position": {"lat": 68.1234, "lon": 14.5678},
  "character": "Fl W 12s",
  "range_nm": 17
}
```

and the list can be filtered on the command line:

```
$ curl -s https://example.org/lights.json | jq '.[] | select(.range_nm > 15) | .station'
```

The station was modernised in stages. A clockwork rotation mechanism replaced the hand-cranked one in 1902, an acetylene burner arrived in 1923, and electricity followed in 1951, carried across the sound on a cable that the fishermen swore would never hold.
